$X$  = # of customers that get their own hat back

$x_i$  = Indicator Random Variable associated with the event that customer  $i$  gets their own hat back

$x_i = I\{\text{customer } i \text{ gets their hat back}\} = \begin{cases} 1 & \text{if they do} \\ 0 & \text{if they don't} \end{cases}$

$E[x_i] = \Pr(x_i \text{ gets their hat back})$

$$= \frac{1}{n}$$

$$E[X] = E\left[\sum_{i=1}^n x_i\right]$$

$$= \sum_{i=1}^n E[x_i]$$

$$= \sum_{i=1}^n \frac{1}{n}$$

$$= \frac{n}{n} = 1$$

the expected # of customers who will get their own hat back is 1

Indicator Random Variable: The variable that  $A[i] > A[j]$ ; 1 if true, 0 if not ( $A[i] < A[j]$ ). Since the permutation is uniform random, we know nothing about the array except that all the numbers are distinct. In that case, the probability of the variable being true is  $1/2$  and also  $1/2$  for false.

$$E[X] = E \left[ \sum_{i=1}^{n-1} \sum_{j=i+1}^n X_{ij} \right] \quad \leftarrow \begin{array}{l} \text{chance of variable holding true} \\ \text{Indicator random variable} \end{array}$$

from 1 to  $n-1$   
in array because  
last element cannot  
be compared to itself

comparison of  
next element to first  
element all the  
way to  $n$

$$= \sum_{i=1}^{n-1} \sum_{j=i+1}^n E[X_{ij}] = \sum_{i=1}^{n-1} \sum_{j=i+1}^n \frac{1}{2} = \sum_{i=1}^{n-1} \left( \frac{1}{2} (n - (i+1) + 1) \right)$$

$$= \frac{1}{2} \sum_{i=1}^{n-1} (n-i) = \frac{1}{2} \sum_{i=1}^{n-1} n - \frac{1}{2} \sum_{i=1}^{n-1} i = \frac{1}{2} [n \cdot (n-1)] - \frac{1}{2} \left[ \frac{1}{2} (n-1)(n) \right]$$

$$\begin{array}{c} 1 + 2 + \dots + n-2 + n-1 \\ n-1 + n-2 + \dots + 2 + 1 \end{array}$$

$$2\Sigma = (n-1)n$$

$$\Sigma = \frac{(n-1)(n)}{2}$$

$$\begin{aligned} &= \frac{1}{2} [n^2 - n] - \frac{1}{2} \left[ \frac{1}{2} (n^2 - n) \right] = \frac{1}{2} \left[ n^2 - n - \frac{1}{2} n^2 + \frac{1}{2} n \right] \\ &= \frac{1}{2} \left[ \frac{1}{2} n^2 - \frac{1}{2} n \right] = \frac{1}{4} [n^2 - n] = \frac{n(n-1)}{4} \end{aligned}$$

```
PERMUTE-WITH-ALL(A)
```

```
1  n = A.length
```

```
2  for i = 1 to n
```

```
3      swap A[i] with A[RANDOM(1, n)]
```

Does this code produce a uniform random permutation? Why or why not?

Let  $n = 3$ , then there are  $27$  possible outcomes of calling permute-with-all. Assume permute-with-all produce a uniform random permutation, then  $3! = 3 \times 2 \times 1 = 6$ , for each permutation would occur  $\frac{1}{6}$  times.

So each permutation have to occur  $i$  times, but no integer  $i$  can satisfies  $\frac{i}{27} = \frac{1}{6}$ .

from above we know this code does not produce a uniform random permutation.

4. a. Partition will return  $q=r$  so, with all elements in the array being equal, the recurrence will be  $T(n) = T(n-1) + \Theta(n) + T(0)$  for the running time.  
 $\therefore T(n) = \Theta(n^2)$

b. Partition' (A, p, r)

```

1  x = A[p]
2  i = h = p
3  for j = p+1 to r
4      if A[j] < x
5          y = A[j]
6          A[j] = A[h+1]
7          A[h+1] = A[i]
8          A[i] = y
9          i = i + 1
10         h = h + 1
11     else if A[j] == x
12         exchange A[h+1] with A[j]
13         h = h + 1
14     return (i, h)

```

c. Randomized-Partition (A, p, r)

```

1  i = Random(p, r)
2  exchange A[r] with A[i]
3  return Partition' (A, p, r)

```

d. Quicksort' (A, p, r)

```

1  if q < r
2      (q, i) = Randomized-Partition' (A, q, r)
3      Quicksort' (A, p, q-1)
4      Quicksort' (A, i+1, r)

```

d. Any elements that are equal to the pivot should be put in the same partition as pivot because we don't recurse on those elements. So the subproblem size with Quicksort isn't larger than the subproblem size of Quicksort even with equal elements.
