

### Matrix Chain Multiplication

- Problem
  - Find an optimal *parenthesization* of matrix chain multiplication
- Matrix chain multiplication
  - $M = M_1 M_2 \dots M_n$
- Parenthesization
  - A product of matrices is fully parenthesized if it is either a single matrix or the product of two fully parenthesized matrix products, surrounded by parentheses

### Example

- The product of  $M_1 M_2 M_3 M_4$  can be parenthesized in five distinct ways

$$\begin{aligned} & (M_1 (M_2 (M_3 M_4))), \\ & (M_1 ((M_2 M_3) M_4)), \\ & ((M_1 M_2) (M_3 M_4)), \\ & ((M_1 (M_2 M_3)) M_4), \\ & (((M_1 M_2) M_3) M_4) \end{aligned}$$

### Cost of matrix multiplication

- The cost of matrix multiplication is dominated by scalar multiplications.
- The cost of multiplying a  $p \times q$  matrix with a  $q \times r$  matrix is  $pqr$

```
for (i=0; i<p; i++)
  for (j=0; j<r; j++) {
    C[i][j] = 0;
    for (k=0; k<q; k++)
      C[i][j] += A[i][k]*B[k][j];
  }
```

### Why parenthesization is important

- Consider a chain  $\langle A_1, A_2, A_3 \rangle$  and the dimensions of the matrices are  $10 \times 100$ ,  $100 \times 5$ , and  $5 \times 50$ .
  - Cost for  $((A_1 A_2) A_3)$  is  $10 * 100 * 5 + 10 * 5 * 50 = 7,500$
  - Cost for  $(A_1 (A_2 A_3))$  is  $100 * 5 * 50 + 10 * 100 * 50 = 75,000$
  - One is 10 times faster than the other!

## The Matrix Chain Multiplication

### Problem

- Given a chain of  $\langle M_1, M_2, \dots, M_n \rangle$  of matrices, where for  $i = 1, 2, \dots, n$ , matrix  $M_i$  has dimension  $p_{i-1} \times p_i$ , fully parenthesize the product in a way that  $M_1 M_2 \dots M_n$  minimizes the number of scalar multiplications

## Counting the number of parenthesizations

- We can split a sequence of  $n$  matrices between  $k_{th}$  and  $(k+1)_{st}$  matrices. We obtain the recurrence

$$t(n) = \begin{cases} 1, & n = 1 \\ \sum_{k=1}^n t(k)t(n-k), & n > 1 \end{cases}$$

- The solution is the sequence of *Catalan numbers*

$$t(n) = C(n-1), \quad \text{where} \quad C(n-1) = \frac{1}{n+1} \binom{2n}{n} = \Omega\left(\frac{4^n}{n^{3/2}}\right)$$

## A recursive equation (optimal substructure)

- Let  $m[i,j]$  be the minimum number of scalar multiplications needed to compute  $M_{i..j}$ 
  - The cost for  $M_{1..n}$  is  $m[1,n]$
- Assume that the optimal parenthesization splits the product  $M_i M_{i+1} \dots M_j$  between  $M_k$  and  $M_{k+1}$ 
  - Based on the principle of the optimality
$$m[i,j] = m[i,k] + m[k+1,j] + p_{i-1} p_k p_j$$
  - We obtain the following recurrence

$$m[i,j] = \begin{cases} 0, & i = j \\ \min_{i \leq k < j} (m[i,k] + m[k+1,j] + p_{i-1} p_k p_j), & i < j \end{cases}$$

## Dynamic programming

- We start from each single matrix
- We then calculate the minimum number of multiplications for length  $l$  sequence for  $l = 2, \dots, n$ 
  - The final solution is that for length  $n$

$$\begin{array}{ll} \underline{\underline{M1}} \underline{\underline{M2}} \underline{\underline{M3}} \underline{\underline{M4}} \underline{\underline{M5}} & l=1 \\ \underline{\underline{M1}} \underline{\underline{M2}} \underline{\underline{M3}} \underline{\underline{M4}} \underline{\underline{M5}} & l=2 \\ \underline{\underline{M1}} \underline{\underline{M2}} \underline{\underline{M3}} \underline{\underline{M4}} \underline{\underline{M5}} & l=3 \\ \underline{\underline{M1}} \underline{\underline{M2}} \underline{\underline{M3}} \underline{\underline{M4}} \underline{\underline{M5}} & l=4 \\ \underline{\underline{M1}} \underline{\underline{M2}} \underline{\underline{M3}} \underline{\underline{M4}} \underline{\underline{M5}} & l=5 \end{array}$$

## An implementation using dynamic programming

```

matChain()
{
    for (i=1; i<=n; i++) // sequence of length 1
        m[i][i]=0;

    for (l=2; l<=n; l++) // l is the length of the sequence
        for (i=1; i<=n-l+1; i++) {
            j = i+l-1;
            m[i][j] = ∞;
            for (k=i; k<=j-1; k++)
                tmp = m[i][k]+m[k+1][j]+p[i-1]p[k]p[j]
                if (tmp < m[i][j]) {
                    m[i][j] = tmp;
                    s[i][j] = k; // split point
                }
        }
}

```

Cost:

$$\begin{aligned}
 & n + \sum_{l=2}^n \sum_{i=1}^{n-l+1} (l-1) \\
 &= n + \sum_{l=2}^n (n-l+1)(l-1) \\
 &= n + \sum_{j=1}^{n-1} (n-j)j \\
 &= n + n \sum_{j=1}^{n-1} j - \sum_{j=1}^{n-1} j^2 \\
 &= n + \frac{n^2(n-1)}{2} - \frac{n(n-1)(2n-1)}{6} \\
 &= (n^3 + 5n) / 6 \\
 &\in \Theta(n^3)
 \end{aligned}$$

## Example

M1	13×5
M2	5×89
M3	89×3
M4	3×34

i \ j	1	2	3	4
1	0	5785	1530 <sub>1</sub>	2856 <sub>3</sub>
2		0	1335	1845 <sub>3</sub>
3			0	9078
4				0

$m[1][3] = \min(m[1][1] + m[2][3] + 13 \cdot 5 \cdot 3, m[1][2] + m[3][3] + 13 \cdot 89 \cdot 3) = \min(1530, 9256) = 1530$   
 $m[2][4] = \min(m[2][2] + m[3][4] + 5 \cdot 89 \cdot 34, m[2][3] + m[4][4] + 5 \cdot 3 \cdot 34) = \min(24208, 1845) = 1845$

$\min[1][4] = \min(m[1][1] + m[2][4] + 13 \cdot 5 \cdot 34, \quad k=1$   
 $\quad m[1][2] + m[2][4] + 13 \cdot 89 \cdot 34, \quad k=2$   
 $\quad m[1][3] + m[4][4] + 13 \cdot 3 \cdot 34) \quad k=3$   
 $= \min(4055, 54201, 2856) = 2856$

## Construct the optimal parenthesization

- In our algorithm, the matrix  $s$  tracks the split point
  - Can you use the matrix to construct the optimal parenthesization?

```

PrintOptimalParens(s, i, j)
{
    if (i==j)
        print ("M", i)
    else {
        print("(");
        PrintOptimalParens(s, i, s[i][j]);
        PrintOptimalParens(s, s[i][j]+1, j);
        print(")")
    }
}

```
